PRESENTED BY THE ICMAT DIFFERENTIAL - GEOMETRY AND GEOMETRIC MECHANICS GROUP 17
The convexity theorem for the momentum polytope was widely generalised by Fields medal and Abel prize winner Michael Atiyah, Leroy P. Steele prize winner Victor Guillemin, and Savillian Professor of Geometry at Oxford, Frances Kirwan and celebrated mathematician Shlomo Sternberg.

One of the reasons to which we can attribute this concentration of talent is that describing the image of a momentum map defined on a symplectic manifold has generated a large amount of research and remains, to this day, one of the most active areas in symplectic geometry.

The Instituto de Ciencias Matemáticas (ICMAT) is pleased to host the first Symposium on New Developments in Momentum Polytope Theory from July 26 to July 30, 2021 - followed by the first Summer School on New Developments in Momentum Polytope Theory from August 2 to August 5, 2021.

There have not been any summer schools solely focussed on momentum polytope theory, but there are researchers across the world who are or have been working on it. Therefore, this symposium and school is to bring everyone up to speed with current state-of-the-art developments, methods and applications.

We have speakers from all variety of backgrounds with one focal point: momentum polytope theory.

We hope you enjoy the symposium and the school.

**Hamiltonian multiplicity-free manifolds**

The first lecture deals with some basic definitions and results on Hamiltonian multiplicity-free manifolds acted on by a connected compact Lie group. In the second lecture, we shall focus on the momentum polytopes of the compact connected Hamiltonian multiplicity-free manifolds and some of their generalizations.

Alvaro Pelayo  
*Universidad Complutense de Madrid, Spain*

**Introduction to symplectic geometry of integrable Hamiltonian Systems**

This minicourse will give an overview of some of the basic concepts of symplectic geometry and the theory of integrable Hamiltonian systems, with an emphasis on the construction of symplectic invariants.
The Delzant construction assigns a symplectic toric manifold to each smooth convex polytope. If the polytope is simple and rational, but not smooth, the Delzant construction yields symplectic toric orbifolds. Symplectic toric quasifolds, on the other hand, were introduced in 1999 in order to extend this construction to any simple convex polytope. If the polytopes are not rational, these spaces are highly singular, but still retain a lot of the properties of their smooth/orbifold counterparts. In particular, they possess a beautiful atlas, whose charts are given by quotients of open subsets of $\mathbb{R}^{2n}$ modulo the action of countable subgroups of the standard torus $T^n$.

In these lectures, we begin by recalling the Delzant construction and we apply it to a number of examples. We pass on to describing the extension of this construction to the nonrational case. We discuss several examples: the quasisphere, a one parameter family of spaces that generalise Hirzebruch surfaces, the quasifolds associated to the tiles of certain nonperiodic tilings, and to the regular dodecahedron. We conclude by describing the symplectic reduction and the symplectic cutting operations in this setting.

INTEGRABLE SYSTEMS WITH SPHERICAL SINGULARITIES

Integrable systems with spherical singularities possess two remarkable properties: 1) they admit a torus action generated by continuous functions which are smooth everywhere except for singular fibers, 2) singular fibres are smooth Lagrangian submanifolds (e.g. Lagrangian spheres). The image of the momentum map for such a system is a polytop whose (combinatorial and affine) properties are essentially different from those of Delzant polytops. The main issue to discuss is quite traditional in this area: can one reconstruct the system from this polytop?

OPTIMIZATION, COMPLEXITY AND INVARIANT THEORY

Invariant and representation theory studies symmetries by means of group actions and is a well established source of unifying principles in mathematics and physics. Recent research suggests its relevance for complexity and optimization through quantitative and algorithmic questions. The goal of the talk is to give an introduction to new algorithmic and analysis techniques that extend convex optimization from the classical Euclidean setting to a general geodesic setting. We also point out surprising connections to a diverse set of problems in different areas of mathematics, statistics, computer science, and physics.

The talk is mainly based on this joint article with Cole Franks, Ankit Garg, Rafael Oliveira, Michael Walter and Avi Wigderson: http://arxiv.org/abs/1910.12375

**Integrable systems on singular symplectic manifolds**

In this talk, we address the problem of local and global existence of action-angle coordinates for integrable systems in singular symplectic manifolds. Two types of singular geometric structures, whose singular locus is a hypersurface, are considered: b-symplectic manifolds [4] and folded symplectic manifolds [1]. In the b-symplectic case, integrable systems were already introduced and studied in [7]. For folded singularities, we introduce the corresponding Hamiltonian dynamics and the notion of integrability, generalizing folded toric actions [2, 6]. We will present some examples and prove an action-angle coordinate theorem around a regular fiber that lies in the singular hypersurface. Time permitting, we will construct examples in certain b-symplectic manifolds and exhibit topological obstructions to the existence of semi-local action-angle coordinates. The obstructions arise from the topological monodromy of the singular locus of a b-symplectic manifold. By applying a desingularization technique [5], similar statements about folded integrable systems can be deduced. This is joint work with Eva Miranda.

**Effective linear restrictions on the spectrum of 1-reduced constrained operators**

In the 1960’s several authors characterized the set of 1-reduced density operators via a spectral characterization: the spectra must lie in a hypersimplex. We study a constrained version: we focus of 1-reduced density operators arising from density operators with a prescribed spectrum. The spectra of these operators form a moment polytope. We consider a convex relaxation where we symmetrize the polytope and obtain inequalities for this bigger set. Since these inequalities are essentially independent of the number of particles involved, they may be interpreted as generalized Pauli constraints. This is joint work with J.P. Labbe, J. Liebert, A. Padrol, E. Philippe, and C. Schilling.
We wish to understand when a tensor $s$ can be transformed into a tensor $t$ by application of linear maps to its tensor legs (we then say $s$ restricts to $t$). In the language of restrictions, the rank of a tensor $t$ is given by the minimal size of a diagonal tensor restricting to $t$. The study of rank and restrictions are motivated by algebraic complexity theory, where the rank corresponds to the computational complexity of a bilinear map (e.g. matrix multiplication) which then is viewed as a tensor with three legs.

Interestingly, some important open problems can be formulated in terms of asymptotic properties of restriction, among them the exponent of matrix multiplication. Following the seminal work of Volker Strassen, we will therefore study whether for large $n$ the $(n+o(n))^\text{'th}$ tensor power of $s$ can be restricted to the $n\text{'th}$ tensor power of $t$. The information-theoretic flavor of the problem is apparent and was heavily used by Strassen in conjunction with the discovery of algebraic structures (his spectral theorem).

Identifying $k$-leg-tensors with states of quantum systems of $k$ particles allows us to bring tools and ideas from quantum information theory to the table, among them entanglement polytopes and quantum entropy. I will use these to construct a family of functionals - the quantum functionals - that can serve as obstructions to asymptotic restrictions. The functionals are the first of their kind applicable to all tensors, thereby solving a problem by Strassen from 1986.

As is well-known, the momentum polytope of a compact connected Hamiltonian manifold acted on by a connected compact Lie group is a rational convex polytope. My talk deals with these manifolds which are Kähler and multiplicity-free; I shall outline how they can be classified by combinatorial representation theoretical invariants involving their momentum polytopes and in particular how the latter can be characterized.

**Momentum Polytopes related to geodesic flows on spheres**

Separation of variables for the geodesic flows on spheres leads to a large family of integrable systems whose integrals are defined through the separation constants. Reduction by the periodic flow of the Hamiltonian leads to integrable systems on Grassmanians. Specifically for the geodesic flow on the $S^3$ the reduced system defines a family of integrable systems on $S^2 \times S^2$. We show that the image of these systems under a continuous momentum map defined through the action variables has a triangle as its image. The image is rigid and does not change when the integrable system is changed within the family. Each member of the family can be identified with a point inside a Stasheff polytope. Corners of the polytope correspond to toric systems (possibly with degenerations), edges correspond semi-toric systems (in various meanings of the word), and the face corresponds to “generic” integrable systems. A fundamental difference of this momentum map to that of a toric or semi-toric system is that the number of tori in the preimage of a non critical point may be 1, 2, or 4. The momentum map is continuous but not smooth along the images of hyperbolic singularities. The corresponding quantum problem and generalisations to higher dimensional spheres will be discussed. This is joint work with Diana Nguyen, Sean Dawson

Gleb Koshevoy

**Redundancy in string cone inequalities and potential functions on Cluster Varieties**

We give a conjectural equivalence between redundancy of string cone inequalities and multiplicities in potential functions. We prove the if part of the conjecture in general and provide several examples and applications. Join work with Bea Schumann

Gabriel Larotonda  
*Universidad de Buenos Aires, Argentina*

**Finsler geometry of a compact Lie group by means of a momentum polytope.**

In this talk we will discuss the geometry of a compact Lie group $K$ which acts by Hamiltonian diffeomorphisms on a symplectic manifold $M$. Generalized Hofer norms on the Lie algebra of $K$ are a nice way of giving the group $K$ a Finsler geometry by means of the momentum polytope $\mu(M) \subset \text{Lie}(K)$. We will discuss the correspondence between geodesics in the group $K$ and geodesics in the (infinite dimensional) Lie group of Hamiltonian diffeomorphisms of $M$, with its Hofer metric. We will also discuss the correspondence between the geometry of the polytope and certain qualities of the geodesics in $K$. This is joint work with Martin Miglioli.
Eckhard Meinrenken  
*University of Toronto, Canada*

**Convexity for group-valued moment maps**  
I will review the convexity theorem for Lie group valued moment maps, proved around 1998, and describe some of the more recent developments and open questions.

Pau Mir  
*Universitat Politècnica de Catalunya, Spain*

**Rigidity of Contangent lifts and Integrable Systems**  
The theorem by Palais on the rigidity of compact group actions can be extended to cotangent lifts. I will use this result to prove rigidity for integrable systems and their momentum polytopes on symplectic manifolds, including systems with degenerate singularities which are invariant under a torus action. This is joint work with Eva Miranda.

Eva Miranda  
*Universitat Politècnica de Catalunya, Spain*

**From a b-Delzant theorem to geometric quantization and back**  
In this talk I will present a Delzant theorem for b-Hamiltonian toric actions on compact symplectic manifolds.  
The only 2-dimensional toric manifolds are the b-sphere and the b-torus and the only invariants of their classification are the connected components of the critical set, the regularized Liouville volume and the modular weights associated to each connected component. All these invariants can be read off the image of the b-moment map. For higher dimensions, the classification of b-toric manifolds is also given in terms of b-polytopes.  
One of the applications of this classification scheme is that of quantization. In this set-up, we will generalize a theorem by Guillemin-Sternberg which identifies Bohr-Sommerfeld leaves with fibers of the integral points in the image of the moment map and connect it to a sheaf-theoretical approach to Geometric Quantization suggested by Kostant.  
Last but not least, we will retake the formal geometric quantization scheme for b-manifolds (see Jonathan Weitsman’s talk).
Extending circle actions to integrable systems

A Hamiltonian circle action on a symplectic manifold is generated by a single real valued function. Given a compact four dimensional symplectic manifold with a Hamiltonian circle action generated by a function J, when can we find another function H such that (J,H) forms an integrable system? What can we say about the properties of the resulting integrable system (J,H)?

We show that such an H always exists, and moreover that H can be chosen so that all singularities of (J,H) are non-degenerate except for some finite number of parabolic orbits. The case that (J,H) is a toric integrable system was studied by Karshon, and the case that (J,H) is a semitoric integrable system was studied by Hohloch-Sabatini-Sepe-Symington. Due to the topic of this symposium we will emphasize the role that moment polytopes play in this story. This work is joint with S. Hohloch.

Symplectic and Spectral Geometry of Integrable Systems

Integrable systems form a special class of dynamical systems with many conserved quantities and they play a prominent role in both mathematics and physics. In this talk first I will discuss some classical and recent results on symplectic geometry of finite dimensional classical integrable Hamiltonian systems, and then I will make some connections with the spectral geometry of their quantum counterparts.

Towards a polarization-free quantization

We show how a variant of geometric quantization which is free of a choice of polarization may be defined, and also possible problems with this method.

Counting disks in a cubic surface via moment polytopes

The count of twenty-seven spheres in a cubic surface by Cayley-Salmon was a prominent result of nineteenth century mathematics. I will explain this computation, and a more modern computation of the count of twenty-one disks in the cubic surface bounding a Lagrangian torus from the point of view of moment polytopes and tropical geometry. The count plays a role in the construction of the mirror to the cubic surface. This is joint with Sushmita Venugopalan.
Sean Dawson  
*University of Sydney, Australia*

**Monodromy in Prolate Spheroidal Harmonics**

We show that separating the free particle in R3 in prolate spheroidal coordinates gives an integrable system that exhibits quantum monodromy. Using an analogue of the Laplace-Runge-Lenz vector we show that this classical Liouville integrable system is symplectically equivalent to the C. Neumann system.

We explore the various quantum and classical properties of this system. By finding the momentum map, we show that this is a generalised semi-toric system with a non-degenerate focus-focus point and so there is monodromy in both the classical and the quantum systems. Additionally, we investigate the spheroidal wave functions (the eigenfunctions of the corresponding two commuting operators on L2(S2)) as well as the resulting joint spectrum and action map. To our knowledge, this is the first explicit demonstration that quantum monodromy exists in a class of classically known special functions. A similar phenomena also appears when separating the geodesic flow in prolate coordinates on S3. To appear in Stud. Appl. Math. (2021), arXiv:2001.11270

This is joint work with Holger Dullin and Diana Nguyen.

Anastasia Matveeva  
*UPC, Spain*

**Singular Symplectic Geometry: Moment Maps and Reduction**

In this poster we will start some introduction to singular symplectic geometry. In particular, we study b- and bm-symplectic manifolds (that can be seen as symplectic manifolds with boundary) together with the associated group actions. Focusing on moment map theory we are going to obtain an analogue of Hamiltonian reduction for bm-symplectic manifolds. This is joint work with prof. Eva Miranda.

**INTEGRABLE SYSTEMS ARISING FROM SEPARATION ON $S^3$**

It is known from Schöbel and Veselov [CMP 337, p1255] that the algebraic variety of separable coordinates on $S^3$ can be represented as a Stasheff polytope. The most general of these are the ellipsoidal coordinates and the 5 degenerate systems are prolate, oblate, Lame-subgroup reduction, spherical and cylindrical. In this presentation we investigate the various integrable systems arising from separating the geodesic flow on the round sphere $S^3$ in these coordinates. By symplectic reduction of the geodesic Hamiltonian we obtain corresponding integrable systems on the reduced space $S^2 \times S^2$. We show that the image of the corresponding action map for each system has a Delzant triangle as the boundary even though most of the systems is the family are not toric. Resounding similarities are found between the momentum maps of our systems and those from the geodesic flow on an ellipsoid and the Neumann problem. We also show preliminary results from our study of the corresponding quantum systems.  

This is joint work with Sean Dawson and Holger Dullin.
